Abstract

As edge computing shifts toward biological architectures, Brain-Computer Interfaces (BCIs) and autonomous robotics increasingly rely on Spiking Neural Networks (SNNs). However, these event-driven chips remain catastrophically vulnerable to physical Side-Channel Attacks, specifically Electromagnetic Fault Injection (EMFI). This paper introduces the Balam Protocol: a runtime firmware layer that mathematically filters malicious analog voltage glitches in real-time, preserving temporal membrane integrity without compromising ultra-low latency operations.

1 The Threat Model: Digital Seizures

Unlike traditional von Neumann architectures, SNNs do not rely on a global clock. They process asynchronous spikes. A hacker utilizing an EMFI tool can inject localized magnetic interference to artificially raise the membrane potential of a Leaky Integrate-and-Fire (LIF) neuron. This bypasses traditional software firewalls entirely, resulting in a continuous, uncontrollable spike train—a digital seizure that can cause kinetic destruction in edge devices.

2 The Balam Architecture

The Balam Protocol acts as a biological shield embedded before the synaptic computation layer. By continuously monitoring the incoming voltage against standard biological thresholds, it clamps malicious energy injections before they breach the membrane potential limits.

3 Experimental Results

In a simulated environment utilizing PyTorch and snnTorch, a target SNN was subjected to a simulated 5.0v EMFI pulse. As demonstrated in Figure **??**, the unprotected neuron (red) exhibited catastrophic failure, spiking continuously. Upon activation of the Balam Protocol (green), the malicious pulse was mathematically neutralized, restoring the membrane potential to safe, operational levels.

4 Conclusion and Future Work

The software Proof of Concept confirms that runtime anomaly filtering is highly effective for SNNs. The next phase of Project Balam involves translating this PyTorch logic into VHDL/Verilog to test ultra-low latency execution directly on FPGA silicon.
